

Library $\mathcal{C}$
19 rules, including
the null action π_0

Paired estimates
 $\bar{\Delta}(\pi)$ and $\text{se}(\pi)$
on $n \approx 80$
calibration items

Corrected bound
 $L(\pi) = \bar{\Delta}(\pi)$
 $- t_{1-\alpha/|\mathcal{C}|} \text{se}(\pi)$

Admitted set
every π with
 $L(\pi) \geq -\varepsilon$

Deployed rule
 $\hat{\pi}_d$, the cheapest
admitted rule

selecting the best of 19 estimates is optimistic, so each interval is widened by the Bonferroni factor at $\alpha = 0.10$

the set is never empty, because $L(\pi_0) = 0$; the certificate is valid while calibration and deployment items are exchangeable

A distribution-free bound would be far wider at this sample size: at $n = 80$ a Hoeffding interval admits nothing but the null action (Section 3.5).
